- Consider data for 100 medical conditions from the Integrated Medical Evidence Database (iMED)
- Simulate medical event occurrences over large number of missions via Monte Carlo methodology
- For each medical condition:

- **Best practices with computer modeling includes establishing the robustness of the model**
- **Robustness is the determination of how thoroughly the sensitivities of the model results to the variables and parameters of the model are known**
- **Infers an understanding of the sensitivity of the real-world system to potential changes in the variables and parameters of the system**
 - Assuming the imitated system behaves like the real-world system
- **Understanding the relative importance of variables and parameters, along with the relative ability to affect those variables and parameters, improves decision making**

- **Saltelli: “Sensitivity Analysis is the study of how variation in the output of a model can be apportioned, qualitatively or quantitatively, to different sources of variation (input) and how the given model depends upon the information fed into it.”**
- **Partial Rank Correlation Coefficient (PRCC) Analysis**
 - Provides the linear relationships between two variables (one input parameter and one output parameter) when all linear effects of other variables are removed after rank transformation
 - Rank Transformation: transforms non-linear monotonic relations to linear
- **SRRC – Description goes here**
 - Standardized regression-based coefficients measure the sensitivity of each input on each output, adjusted for all the other inputs
 - Rank Transformation: transforms non-linear monotonic relations to linear

- ***KEEP IN MIND*** the difference between an influential condition and a sensitive condition
 - Many conditions contribute substantially to the mean output of the model
 - Low sensitivity may indicate a “DC-signal effect” over the range of model application and parameter variance
 - Example: VIIP and EVAC
 - Parameter variance affecting model output (magnitude and variance) indicates a sensitive parameter

Using IMM for ISS missions

- **IMM Provides probabilistic analysis of 100 medical condition occurrences and impact to mission outcomes**
- **Context : 32 person-missions representing ISS person-missions of NASA astronauts Expedition 14 and later; also used in RWS validation**
- **Output:**
 - Total Medical Events
 - Crew Health Index (crew available time – time lost due to medical events)
 - Evacuation
 - Loss of crew life

$$CHI = \left(1 - \frac{QTL}{L} \right) \cdot 100\%$$

Total Medical Events

Sensitivity Estimates - Treated Timeline TME

Crew Health Index

Sensitivity Estimates - Treated Timeline CHI

Consideration of Evacuation

Sensitivity Estimates - Treated Timeline EVAC

Sensitivity Estimates - Treated Timeline LOCL

- **Successfully implemented a rigorous quantification of model sensitivity to parameter uncertainty**
 - Differs from and augments influential conditions estimate currently used by IMM
- **Many sensitive conditions in the CHI, EVAC, and LOCL cases do not appear in the sensitivity estimates of the total number of medical events**
 - these conditions having a low incidence rate, so the effect on TME is minimal
 - have a large effect such as prolonged impairment, evacuation, or death

Thank you!
